Task 1: To Be or Not to Be… Online

Global Context: In sports today, '**Identities and Relationships'** focuses on how individuals develop a sense of self-expression, along with the formation of deep, meaningful **relationships** with others. In the modern world, athletes utilize **digital platforms** like social media, training apps, coaching platforms, and team group chats to develop their **relationships** and shape a large proportion of their **identities**. These **online platforms** also can impact, how players express themselves and **communicate** with their athletic community. **Identities and relationships** examine how these online **platforms** aid athletes construct **relationships** with coaches and teammates even outside of direct reciprocity sessions by enabling them to selectively **communicate** training progress, feelings, and personal experiences. Furthermore, by exploring specific facets of their passions, personality, and accomplishments, as individuals have the power to customize how they are perceived in online **interactions**. Athletes can shape their athletic **identity** and reputation within their sports community, for instance, by highlighting training milestones, competition outcomes, or recuperation techniques on social media. Neuroticism extroverts have been proved that they are chronically **online** expressing their **identity** constantly on a device, as results from a sample of 1,094 female Facebook users, aged 18-35 showed that addictive social media use was positively correlated with neuroticism but not extraversion (Marengo et al., 2020). However, individuals have to be careful as these **online** spaces have the potential to affect how people express themselves, show who they area, and form emotional connections within a **digital society**.

Key Concepts: '**Communication**' is the key concept of this E-portfolio which forms the foundation for understanding, connection, and information sharing in athletic **environments**. Athletes' performance and **identity** are ultimately shaped by **communication** through the feedback they get, the connections they make with coaches and teammates, along with the lessons they absorb about success, expectations, and belonging (Hawley, 2024)**.** This can also affect how they learn techniques, receive criticism, and develop connections. From a psychological standpoint, clear and effective **communication** builds confidence, trust, and resilience, while misunderstanding can produce doubt or worry. For instance, coaching and senior management staff must have the capacity to **communicate** effectively to build an optimal **environment** no matter what sport they are coaching for. The primary cause of burnout in young athletes was discovered to be caused by poor **communication**. This was because they felt that their surrounding **environments** were dominating and unduly demanding, leading to athletes experiencing stress (Hanson, 2019).

Related Concepts: '**Environment, interaction'** is fundamental in sports as they influence how athletes practice, perform, and establish their **identities**. With the social **environment -** coaches, teammates and online **communities**, it influences motivation, learning, and emotional support. An athlete's technique, safety, and overall performance results are all directly impacted by the physical **environment**, which includes facilities, equipment, and surfaces. While bad conditions can impair performance and raise safety issues, a well-maintained and appropriate **environment** can improve skill execution and lower the chance of injury. From a psychological standpoint, positive **interactions** within these **environments** help develop confidence and engagements, whereas a negative or unsupportive **environment** can induce anxiety or hamper progress. Peer-to-peer **interactions** like athletes and coaches during practice and competition are crucial for teamwork, skill development, and fluent feedback. Without a strong foundation of **interactions**, it might limit an athlete's growth; studies show that social support contributes 27.90% to athletes' motivation in striving, which is a low number, this can lead to athletes having less social support making them more likely to be less motivated and improve their technical talents along with their sense of self more slowly (Arif Pambudi, N. 2022). However, with the help of **digital platforms** it has been made easier for athletes to **communicate** with a broader sports community and **interact** constantly with their peers.

Statement of inquiry: '**Communication** within a **digital environment** can influence how **identity** and **relationships** are formed' is the statement of inquiry that states that athletes in contemporary sports **communicate** with coaches, teammates, and the larger athletic community using **digital platforms** including social media, video analysis applications, and team messaging systems on platforms like Padlet enables athletes to plan training regimens, talk about tactics, and offer support, promoting social and physical growth (Garrish, 2018). These platforms allow athletes to share progress, express thoughts and emotions, and receive feedback that can help them optimize their performance to the fullest outside of typical face-to-face feedback. This helps influence both their self-perception and how they relate to others with the consistent **communication** flow that can occur more frequently through the use of **digital platforms**. Additionally, selective sharing is made possible by **digital communication** (Content Team, 2025), which helps athletes build their **digital athletic identity** by highlighting accomplishments, asking for guidance, or reflecting back on training through the use of video analysis on **digital platforms** like Hudl or Coach's Eye, which permanently enhances technical awareness and makes it possible to find and mistakes over time to give thoughtful feedback. Athletes show how **communication** in **digital societies** directly affect **identity** formation and the quality of connections within sports by strengthening **relationship** between peers and building a strong foundation of support around the athlete allows them to build confidence through the integration of not only in-person **interactions** but as well online engagement.

Health Analysis

Interview and PAR-Q Analysis: My client is a 15-year-old female who is 164cm (5'4) tall and weighs 55kg, which is near the healthy average for her age; 57kg (Proxim). She has a BMI of 20.4 kg/m^2, being in between the classification of 'normal weight' (18.5-24.9 kg/m^2) (What Is Obesity, 2015), indicating that she is physically in the healthy weight range with a mesomorphic body type, which means that she has the ability to gain muscle easily and is able to maintain a lower percentage of body fat. As mesomorphs tend to have powerful lower-body power, good muscular reactivity, and a slender frame which are all qualities that enable a explosive take-off, quickness in the approach, and an overall greater jump performance, which is critical for high jump. Through the use of the innovative WHOOP app, which my client wears, shows that she typically sleeps on average 7 ½ hours as shown in figure A.5a , which is relatively adequate for her age as suggested quantity of sleep for a 15-year-old female is 9 to 9½ hours (John Hopkins Medicine, 2019). However, the best muscle repair and performance adaptation may be limited by this slightly shorter sleeping time. Furthermore, she has on average 11,000 steps achieved per day as seen in figure A.3a, surpassing the recommended amount of 10,000 steps (Team, 2016), demostrating a high baseline level of regular exercise that enhances overall conditioning and cardiovascular fitness. My client has not been actively using

Figure A.4a

the gym each day, however, she does athletics three times a week, for about an hour, supplying a steady training stimulus to promote movement efficiency and sport-specfic fitness. keeping up a decently active lifestyle. Moreover, her diet is rather balanced as she places a greater focus on taking in her protein and carbohydrates, with consuming around 2,000 calories per day, which meets the average calories that a woman needs per day, encouraging the avaliability of enough energy for exercise and muscle restoration. She drinks on average 80z of water a day, and does not take any suplements like creatine or narcotics, which promotes healthy long-term physical performance, thermoregulation, and hydration. Additionally, I have interviewed my client, asking personal questions about her daily routine, how the **digitial** society plays apart of her life and how it is affected by the **environment** around her, along with her diet. An athlete may find it more difficult to control their arousal and stay focused during a performance if they have a high level of anxiety and a heavy reliance on digital platforms because continual online comparison and external feedback enhance cognitive stress (Doré, 2025), which is why a **digital** detox is essential for my client. The **digital** society is incorprated in her daily routine with a daily average of 7 hours and 45 minutes of screen time, as seen in figure A.4a. This implies that the **digital enviorment** influeces the way she **communicates**, studies, and unwinds. She regularly **interacts** with online platforms such as TikTok and Snapchat, which can disrupt training regimens due to increased screen time, that can shape her athletic **identity** through constant comparison with online athletes influencers, who only display the positive side of athletics. From this, it can affect the kind and quality of information she accesses, indcating her strong connection to the **digital** world. Furthermore, my client previously has suffered regular cramping in her legs after, and sometimes even during, her training sessions. When designing her trainning session, I will take this into consideration by including workouts that build the muscles used in high jump while avoiding motions that could cause cramps.

Figure A.5a

Figure A.3a

From finding out this information, explained above, I have decided to conduct furhter tests which will help me gain a clearer understanding of my clients mental and physciall well-being, potential limitation, and overall readiness for performing. While physical prowess is crucial for high jump, mental well-being is just as important. A poor mental health can result in self-doubt, worry, and a decrease in motivation, whereas a strong mental health aids athletes in maintaining confidence, perseverance, and focus. According to Cleveland clinic, 5% to 35% of elite athletes report having a mental illness (Cleveland Clinic, 2024). Whilst, for college athletes, the numbers are significantly greater. My client is a student-athlete who experiences the same **environment** that college athletes go through, balancing the demands of academics with the rigors of sports. Additionally, the **digital environment** can negatively change peer comparison, social validation, and self-perception, from the **digital setting** and media platforms that intensify these pressures, which can alter how they express their real **identity,** it is especially important for high jumpers, who depend on accuracy, concentration, and the capacity to work independently under duress. In this situation, it is crucial to consistently monitory and promote mental health since building resilience and a good self-image aids athletes in navigating the intricate social dynamics of the online world. Through the combination of questionaries and health assessments, I will be able to analyze and evaluate my client's current physical and mental well-being.

Test+ Relevance	Mark scheme	Client results	Analysis
SCAT	<17: low levels of anxiety 17-24: moderate levels >24: high level of anxiety	Score of 28 – high level of anxiety	My client scored a 28 on the SCAT test, which is located in the high level of anxiety. This implies that she might feel a great level of anxiety, stress, and trouble concentrating during competitions, which might be impacted by their **interactions** in a competitive environment. High anxiety may also affect how she interacts with the **digital society**, such as feedback from coaches or peers, and comparison with professional athletes. As her coach, I will help her control her anxiety throughout practice and competition by teaching her coping mechanisms and relaxation techniques.
BSMASS	The scale is in the rage of 6-12 for modest use, 13-18 for mild worry, 19-24 for moderate addiction risk, and 25-30 for high addiction risk	High addiction	From the BSMASS test, it expresses that my client shows a high level of social media dependence, indicating that **digita**l platforms have significant impact on their everyday behavior, routines and emotions. This implies that my client can find it difficult to unplug or control their internet usage or it can be easier for my client to **communicate** easily on a **digital platform**. Furthermore, this can affect my client's physical well-being, as high screen time and constant online engagement may reduce their motivation, and available time for physical activity, ultimately impacting their overall fitness levels. In my capacity as her coach, I will assist her by establishing clear guidelines for her usage of social media and promoting offline pursuits to enhance her wellbeing and concentration.
ASCI	Higher scores indicate stronger strength on the overall scale, which has a range of 0 to 84	35 (moderately low)	From the ASCI test, my client has a fairly low social connection strength, which means they can feel less connected or supported in meaningful **interactions**. This indicates that even though my client uses social media extensively, it is not giving them great emotional support, meaning she could have a high level of anxiety. In order to promote their overall well-being, as her coach, I will help her develop deeper, more meaningful connections with others both offline and online.
Eysenck personality test	Extroversion Neuroticism Psychoticism	Extroversion-62%	My client has a high percentage in both extroversion and neuroticism, where both is at 62%. This can suggest that they rely on social **environments** for connection and validation as my client's high extroversion indicates that their

		Neuroticism-62% Psychoticism-23%	surrounding and **interactions** strongly influence their behavior. Additionally, their fairly high neuroticism, **communication** in these **interactions** may impact their emotions, making their more sensitive and anxious. As her coach, I will assist her in controlling her emotions in social **environments** and strengthening her resistance to outside influences.

Clients' mental well-being analysis:

My client's mental well-being ratings reflect a fairly balanced state, with most findings falling within the average to high range. However, their lowest result was in the ASCI test, which measures the athlete's coping skills, where she earned a 35 which was classified as moderately low. This shows that although the client works well generally, they may struggle to properly manage stress, pressure, or emotional issues associated to athletics, which can hinder their ability to optimum performance in high jump. According to Self-Determination Theory, the quality of **communication** in an athlete's **environment** can have an impact on their ability to manage stress, pressure, and emotional difficulties, which can affect the potential for improvements as **communication** has the ability to hinder intrinsic motivation from constant negative extrinsic motivation (Standage, 2023). Therefore, in order to stregthen my client's intrinsic motivation and enhance her emotional regulation, as a coach I will concentrate on using supportive, autonomy-enhancing **communication** by offering constructive feedback and promoting self-reflection. Drawing on the cognitive- behavioural theory by Aaron Beck (Chand, Kuckel and Huecker, 2023), poor coping abilities might interfere with attentional control, confidence, and overall emotional regulation, all of which are required for optimal performance (Magazine, 2025). A noticable concern appearing from these findings is the possibility for performance-related anxiety, especially in high-pressure competitive **enviornments**. Based on the Yerkes-Dodson Law resulting in the Inverted U Theory, (Nickerson, 2023) as seen in Figure A.2a at high arousal levels, the quality of performance begins to decline as arousal has been pushed beyond the optimal level, which can be described as panic and fear, hindering the athletes **enviornment** as the social or training surronding can either increase or reduce these stress reactions. (BBC, "Mental Preparation, 2019). Her SCAT socre of 28, which puts her in the high-anxiety category, indicates that her arousal levels are probably higher than the ideal point indicated by the inverted -U Theory, which supports this. Therefore, high levels of arousal might result in poor focus, disturbed technique, and incosistent performance in competitive **enviornments**. To improve the client's mental well-being, coping mechanisms can be incorprated with scientifically backed methods such as deep breathing, visualizaion, and cognitive-behavioural therapy (CBT), all of which help to lessen somatic and cognitive anxiety, which can enable my client to optimize their performance regarding their **interaction** with both their traning **enviornment** and competing surroundings (American Psychological Association, 2017). By introducing psychological interventions such as mindfulness practices, relaxation training, and CBT-based cognitive reframing (Ackerman, 2018) can help reduce these anxieties and improve performance within sports. Furthermore, by utilizing **digital** platforms effciently, clear **communication** between my client and the **digital enviornment** can help establish a postive well-being within the client as extrisitc motivation from platforms can communcate to the client a sense of accomplishment, support, and acknowledgment that boosts self-esteem and inrinsic motivation. Additionally, incorporating goal-setting techniques like SMART goals can boost the client's sense of confiendence, which can help enhance motivation and training participation to furhter optimize their performance.

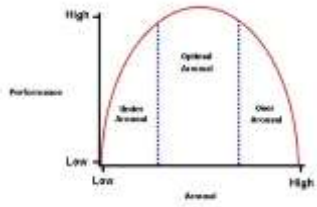

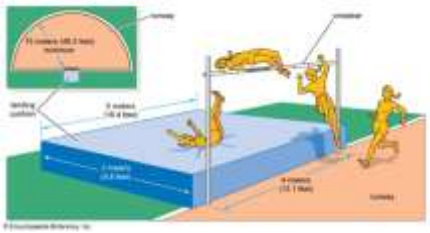

Figure A.2a

Chosen Sport: High Jump: My client has chosen high jump as her athletic event. The athletic event **environment** demonstrates how an athlete forms their sense of **identity** through **interactions**- both with their current surroundings and the online platforms that are presently used for **communication,** teaching, and improvements. As high jump developed, in-person demonstrations gave way to online sports forums, video analysis, and **digital** feedback enhancing the **communication** flow within a **digital society** for both athletes and coaches. The athletic event high jump was initially used in competitive events in the 19th century, and it was originally recorded in Scotland ("High Jump: History, Objective, Events, Equipment & Techniques", 2023). With the development of the high jump, technique was significantly influenced by the **environment** that it was portrayed in. This was because athletes competed on firm surfaces like sand or sawdust pits, which needed safter, upright landings, earlier techniques like the eastern cut-off, straddle, and western roll that were employed ("High Jump: History, Objective, Events, Equipment & Techniques", 2023). It was not until Dick Fosbury created the Fosbury Flop at the Olympics in Mexico City in 1968 (McAlister, 2023) because of the changing **environment** in the 1960s with the introduction of the thick foam mats, enabled a safer option for high jump athletes to experiment new techniques. The four interrelated phases of the high jump are known as approach, takeoff, flight, and landing which all contribute to the jump's success (World Athletics, 2021).

Key phases:

Approach: To maintain the curve and create angular momentum during the curved run-up, the femur adducts as the hips and truck tilt slightly inward. The lower body muscles drive the ankles to dorsiflex at foot strike and plantarflex at push-off, while the knees alternate between flexion and extension. In the approach phase, athletes aim to achieve 8-12 strides until they enter the take-off phase in a J-shaped run towards the high jump bar. (World Athletics, "High Jump", 2021)

Take-off: To gradually reduce the center of mass, the penultimate step takes 10-15% longer than usual. With the foot landing 20-24 cm ahead of the torso and a takeoff angle of roughly 16-22 degrees. They generate additional lift by forcing the opposing knee and arm upward to create counter-rotation and push forcefully away from the ground with the take-off foot, created a vertical impulse through quick hip-knee-ankle extension. (World Athletics, "High Jump", 2021)

Flight: The takeoff velocity and angle dictate the jumper's body's curved (parabolic) trajectory during the flying phase. The Fosbury flop technique involves a deep spinal extension that arches the back and permits the legs to clear last, as the heat and shoulders begin to rotate around the center of mass. (World Athletics, "High Jump", 2021)

Landing: The athlete descends in a controlled flexion after clearing the bar, landing safety in a supine position. (World Athletics, "High Jump", 2021)

Fitness components:

Speed	Speed is the ability to move from one place to another as fast as possible using your entire body, arm, or leg (Miller, 2021). At take-off, the athlete's flight path of the centre of gravity is determined by the take-off angle and approach speed. A jump will generallly be higher when the athlete approaches the bar at their fasted acceleration pace, which is speed that is controlled and effectively directed during take-off (IAAF, 1996).
Muscular Power	One the most important aspect of high jump is power, especially in the legs, and particularly during the takeoff phase. The athlete must produce the maximum amount of explosive force in the smallest period to raise their body vertically as they plant their take-off foot and drive their knee upward. Power enables the athlete to push hard against the ground, defying gravity and raising the body high enough to execute the Fosbury flop successfully, as for higher heights, power is therefore an essential element. (*Objective of High Jump, n.d*)
Strength	Strength is defined as the amount of force a muscle can produce or its capacity to apply force and overcome resistance (BBC, 2019). In high jump, strength in the lower body is essential because it provides the explosie power required to go against gravity, propel the athlete forward, and absorb pressures after take-off. Stronger arm, leg, hip, and core muslces enable a jumper to leap higher by accelerating more quickly using a strong arm swing, and producing a more forceful takeoff.
Flexibility	Flexibility is the capacity of a joint or group of joints to move through an unlimited, pain-free range of motion (UC Davis Health, 2023). The more powerful and flexible a high jumpers muscles are in the hips, legs, arms, and shoulders, then the greater their high jump will be. ("High Jump / High Jumps / Track and Field", 2019). With a higher percentage of flexibility, it will enable the athlete in the jump to have a stronger and controlled arch at the thoracic spine, making it easier to clear the bar without a possibility of the gutelus intiating contact with the bar.

Women's World Record:

At the Paris Diamond League on July 7, 2024, Yaroslava Mahuchikh cleared 2.10 meters, setting a new world record for women's high jump. (worldathletics.org, n.d.)

Type of fitness test	Purpose	Test 1	Test 2	Test 3	Average	Normative score
Vertical Jump test	To measure muscular power in the leg	0.37m	0.34m	0.28m	0.33m	My clients vertical jump power's average is at a fair level (31.0cm)-34.9cm)
30m sprint	To measure acceleration	05.08s	05.29s	05.38s	05.25s	My client's 35m sprint is at an excellent level (> 00:05.30)
Standing Long Jump	To measure strength	1.90m	1.75m	1.80m	1.82m	My client's standing long jump average result is at an excellent level (1.66m-1.85m)
Sit and Reach Test	To measure flexibility	19cm	25cm	25cm	23cm	My client is at an average range (23-28cm)
High Jump Performance	Baseline height	1.24m	1.25m	1.25cm	1.25cm	N/A

My client's performance was analyzed and compared to a professional high jumper, through the use of innovative and technological tools from **digital** platforms like Angle Meter. This app enabled me as a coach, to gain precise measurements of each movement of my client, to point out their strengths and weaknesses in comparison to the professional high jumper, Blanka Vlasic from Croatia.

Phases	Professional Performance-Blanka Vlasic from Croatia	Client's technique	Analysis
Phase 1: Approach/ Run-up			During the approach phase, the professional athlete exhibits a long, rhythmical stride pattern with high horizontal velocity allowing Vlasic to effectively engage her hip extensors, quadriceps, and ankle plantar flexors to generate power in her run. However, my client demonstrates shorter and irregular strides with limited hip extension and a lower knee flexion at 148 degrees compared to Vlasic's 155 degrees. This limits acceleration by reducing speed and power, as reduced limb restricts energy transfer into the take-off phase. Furthermore, the insufficient plantarflexion at the ankle reflects poor explosive strength and coordination, resulting in inefficient ground contact further decreases a build of momentum affecting her vertical lift and performance for high jump,

Phase 2: Take-off			In the take-off phase, the professional achieves ideal joint angles, such as her hinge joint in her elbow that enable the athlete to perform hand-eye coordination. Including a tight knee angle as well of 74 degrees, an open hip position, and controlled shoulder alignment, which shows a perfect execution of the take-off phase. On the other hand, my client displays a lower level of knee flexion; however, she performs a strong 90-degree knee drive which helps to a higher takeoff height by increasing vertical impulse. Furthermore, she has a forward-tilted shoulders which can impact upper-body rotation and balance during the phase which can lower the effectiveness of force transfer from the lower body, limiting overall jump height. The ankles also display a reduced plantarflexion which lowers the explosive push-off from the ground and propulsion.
Phase 3: Flight			Throughout the flight phase, Vlasic maintains an elevated arch over the bar, creating an obtuse angle, along with neutral head posture which facilitates a smooth rotation over the bar by assisting her in maintaining balance and body alignment through a controlled cervical spine engagement. However, comparing this to my client's performance she demonstrates less coordinated flight mechanics, with an early hip fall which can increase the risk of contact with the bar and swinging, uncontrolled arms due to scapular instability which inhibits rotational control and reduces balance. Additionally, she has incomplete leading leg extension which can restrict vertical lift and decreases the chance to clear the bar as a lower leg can hit the bar easier.
Phase 4: Landing			In the landing phase Vlasic absorbs impact safety with straight legs facing upwards and dorsiflexed ankles along with a controlled spinal flexion posture which reduces the risk of injury and stress on the tibiofemoral, talocrural, and spinal joints. This can reduce the chances of affecting an optimal performance in high jump, especially during competitive environments. However, my client initiates contact with the mat in a more rigidly posture, slightly bent knees and uncoordinated ankle dorsiflexion. This is incredibly dangerous, as it can increase the potential for an injury and place stress on the thoracic spine and scapular complex.

Relevant Solutions: Justification for the activities chosen for training plan

Training methods

Plyometric training: It is a technique that trains the muscle's stretch-shortening cycle using high-impact, explosive motions to increase muscle power and speed. This training approach was selected because it works very well for athletes who must produce their maximal force quickly, like in high jump competitions (Walker, 2023). This is because plyometrics closely mimic movements unique to a given discipline, gains can be immediately applied to performance to increase explosive power and boost overall performance. Furthermore, I've incorporated plyometric training into my training regimen with exercises like box jumps, bounding and tuck jumps. Resistance training: It is a type of exercise that builds muscle strength, power, and endurance by using external resistance, such as weights or even bodyweight. This approach has been selected because stronger athletes can use more force, which is crucial for enhancing performance in power-based sports. Resistance training is also simple to track and gradually overload (Taylor, 2022). In order to build important muscle groups involved in performance, I have incorporated resistance training to the training regimen by incorporating exercises like squats, lunges, and pull motions. Dynamic training: It entails deliberate motions that progressively increase intensity while allowing muscles and joints to move through their whole range of motion. This training approach was selected because it increases blood flow, flexibility, and neuromuscular coordination, all of which help the body get ready for physical activity. Dynamic training improves movement efficiency and lowers the chance of injury (Sportamore.com, 2025). To make sure my client is physically ready for training, I have incorporated dynamic training into the warm-up portion of every session utilizing activities like leg swings, arm circles, and walk lunges. Static stretching: In order to improve flexibility and lessen muscle tension, static stretching is a training technique that entails maintaining a stretch for an extended amount of time. This approach was selected because it promotes recuperation and preserves joint range of motion following rigorous training sessions (Millis and Levine, 2014). This is because it

allows muscles to relax, static stretching works best during the cool-down period. In order to promote recovery and avoid muscle tightness, I have started static stretching at the conclusion of each workout, focusing on the main muscle groups engaged during training. Technical drills: It is a type of training that concentrates on improving movement patterns and skills unique to a given sport (Technical Drills, n.d.). This approach has been selected because it maximizes performance and minimizes energy waste. Athletes can increase accuracy and consistency by breaking down movements into phases through technical drills into the training plan, emphasizing important technical components like timing, phase transitions, foot placement, and body stance.

Psychological Skills Training

Visualization: An athlete uses visualization, a mental training technique to construct detailed and vivid mental images of themselves practicing their sport-specific talents. This method was selected because it boosts confidence and concentration by enabling the athlete to mentally practice a performance without really moving (Editorial Team, 2025). Furthermore, this method facilitates mental **communication,** enabling the athlete's ideas, feelings, and bodily movements to cooperate efficiently. From implementing this into the health sessions, my client can develop her **identity** as a competent and self-assured performer by visualizing achievement on a regular basis. This can improve her **interactions and relationships** with teammates, coaches, and fans. As she grows more at ease functioning in competitive **environments,** this mental practice also enhances **environmental interaction.** Progressive muscular relaxation: In order to ease physical stress and anxiety, progressive muscular relaxation is a relaxation technique that entails tensing and then gradually relaxing various bodily muscle groups. This method was selected because it teaches my client how to properly release tense muscles brought on by stress, as she suffers from an above average performance anxiety (Nunez, 2020b). Before sessions, I've used progressive muscular relaxation to assist reduce arousal, increase focus of the **environment,** and stop anxiety from impairing technique and performance. This method enables my client to enhance her **relationship** with stressful performance **environments** by gaining a greater comprehension of how her body **interacts** with surrounding. Breathing techniques: By concentrating on calm, deep, and regulated breathing patterns known as breathing methods are a psychological skill used to regulate arousal levels. This method has been selected since it lowers heart rate and controls anxiety's physical and mental symptoms (Hopkinsmedicine.org, 2024). This is pertinent to my client because nervousness can impair concentration and self-assurance when performing in a crowded **environment**. Before the sessions I have employed breathing exercises like box breathing to help my client be composed, concentrated, and mentally ready to give her best effort. As this method additionally enhances internal **communication,** which can aid my client to have the ability in managing her anxiety levels when **interactin**g with high-pressure **environments.** Mindfulness training: A psychological method called mindfulness training helps athletes to stay in the present and be completely conscious of their feelings, thoughts, and physical experiences without passing judgment. This method was selected because it aids athletes in stress management, which my client lacks in and lessens overthinking, optimizing focus during competition (Mayo Clinic Staff, 2022). My client gains emotional control and a stronger sense of her **identity** by receiving ideas without passing judgment. This is because she is less impacted by external pressure and expectations, this clarity also enhances her **relationships and interactions,** which is why I've implemented this training method into the sessions. Brown Noise: It is the sound produced by sporadic, low frequency movement that muffles distracting sounds and thoughts. The sound of gushing waterfalls, heavy rain, and waves smashing are a few of the instances of brown noise (Yogasleep, 2023). I made my client to listen to it during the training session, to lessen the risk of her anxiety levels to rise and affect her training which would affect her overall performance. From this can help my client become less overwhelmed by the pressure of performing and concentrated more on her technique. Positive Reinforcement: This involves rewarding positive behaviors to make them more likely to be repeated in sports (Ackerman, 2019). As a coach, I decided to employ this strategy to boost my client's self-esteem by continuously praising her development throughout each session. I made careful to draw attention to each gain she made, whether it was technique or gym sessions, so she would know that her efforts were paying off.

Summary:

As a coach, I've discovered that my client's high anxiety and poor coping mechanisms are the main obstacles that are limiting her from succeeding in optimizing her performance in high jump. These factors affect her self-assurance, concentration, and capacity to perform well under pressure. Furthermore, technical inefficiencies in her take-off and her flight phase limit her complete performance, and her heavy use **of digital** platforms impact her ability to control her emotions and self-perception from how the **digital environment** has shaped how she reflects her **identity**. To improve these areas, I will create both physical and mental well-being training programs that can improve her performance in both aspects of well-being. With improving her flexibility and muscular power for her physical performance and aiding her in maintaining control of her high anxiety level that affects her from performing at her optimal level due to arousal levels being higher than moderate levels of anxiety. To monitor her improvement in her performance for high jump, **communication** within a **digital** platform will be initiated to keep constant **interaction** between me as a coach and her as my client.
